## Chapter 2 Math Notes GM7-2018

These notes are provided AS IS and as a convenience only. They are not all-inclusive. Mr. Adey does not guarantee the accuracy of the information provided herein and reserves the right to update or change these notes without notice.

## Percents, Fractions, Decimals

A percent is a ratio that compares a number to 100 .

## To write a percent as a decimal

Write each percent as a fraction with a denominator of 100 . Divide by 100.
$36 \%=36 / 100=36 \div 100=0.36$

## To write a percent as a fraction in simplest form

Write each percent as a fraction with a denominator of 100 . Simplify, if possible.
$36 \%=36 / 100=18 / 50=\mathbf{9} / \mathbf{2 5}$

## To write a fraction as a decimal or percent

Divide the numerator by the denominator. Divide to the thousandths place (if possible) and round to the hundredths place.
$4 / 15=4 \div 15=0.266$. Round up to 0.27 . This is $27 \%$

## To find a percent from a mixed number

## Method 1:

Convert the mixed number into an improper fraction, then divide to find the decimal. Convert that answer into a percent.

## Example:

$1 \frac{1}{5}=\frac{6}{5}$
Divide numerator by denominator: $6 \div 5=1.2$
Multiply by 100 to get the percent $1.2 \times 100-120 . \mathbf{1 2 0 \%}$

## Method 2:

1) Find the percent for the fractional part.
2) Convert the whole number part into a percent by multiplying by 100 .
3) Add these two parts together to get the total percent.

## Example:

$3 \frac{4}{10}=\frac{4}{10}=4 \div 10=0.4=\mathbf{4 0} \%$
$3 \times 100=300=\mathbf{3 0 0 \%}$. Add $\mathbf{4 0 \%}$ to $\mathbf{3 0 0 \%}$ to get $\mathbf{3 4 0 \%}$

## Method 3:

1) If you have a fraction that can be easily converted to 100
a. Write the mixed number as an improper fraction
b. Multiply numerator and denominator by the same number to get the denominator equal to 100
c. The new numerator is your percent.

## Example:

$3 \frac{4}{10}=\frac{34}{10} \times \frac{10}{10}=\frac{\mathbf{3 4 0}}{\mathbf{1 0 0}}=\mathbf{3 4 0 \%}$
To find percent of a number, rewrite the percent as a decimal. Multiply the decimal by the whole number.

Example: Find $22 \%$ of 288
$22 \%=0.22$
$0.22 \times 288=63.36$
So $22 \%$ of 288 is 63.36

## Estimating Percents

We estimate most with percents when we are working with taxes, tips, and discounts.
Most tax rates in the country are no more than $10 \%$.
Use $10 \%$ as a base rate for taxable items. Note: A few products and most foods are taxed at a different rate, or not at all.

Example 1: You buy a shirt that costs $\$ 26.00$. To find $10 \%$ of $\$ 26.00$, simply move the decimal place one spot to the left. $10 \%$ of $\$ 26.00$ is $\$ 2.60$. ADD that to the original amount. $\$ 26.00+\$ 2.60$ and your total should be around $\$ 28.60$.

## Example 2:

To find a normal tip (15\%) on a restaurant bill of $\$ 25.20 \ldots$
First, round $\$ 25.20$ to $\$ 25$
Next, find $10 \%$ of $\$ 25$. Move the decimal over one place to the left: $\$ 2.50$ That is $10 \%$. Next, find half of that number $(\$ 2.50 \div 2=\$ 1.25)$. This is $5 \%$. Add the two amounts $(10 \%+5 \%=15 \%), \$ 2.50+\$ 1.25$ is $\$ 3.75$. So the normal tip on $\$ 25$ is $\$ 3.75$.

## Example 3:

You have a coupon for $20 \%$ off an item. The item is $\$ 15.00$. How much will the item cost altogether?

Since $10 \%$ of $\$ 15.00$ is $\$ 1.50, \mathbf{2 0 \%}$ is twice that amount $\ldots \$ 3.00$
$\$ 15.00-\$ 3.00=\$ 12.00$
But, there is tax on it, too.
$\$ 12.00 \times 10 \%=\$ 1.20 . \$ 12.00+\$ 1.20=\$ 13.20$. So the total should be about $\$ 13.20$

## Is/Of Equation (or Percent Proportion)

$\frac{i s}{o f}=\frac{\%}{100}$
or $\frac{\text { part (or } n \text { if you don't know) }}{\text { whole (or n if you don't know) }}=\frac{\%(\text { or } n \text { if you don't know) }}{100<--- \text { always } 100}$
Cross-multiply the number numbers that are diagonal from each other and then divide by the number that does not match up diagonally with another number to solve

## Example 1:

What is $20 \%$ of $\mathbf{1 5 0}$ ?
$\frac{\text { ?or } n}{150}=\frac{20 \%}{100}$

Multiply 20 by $150=3,000$
Divide by 100 to find $n$ (the "is") $=30$

## Example 2

15 is what percent of 90 ?
$\frac{15}{90}=\frac{? \%}{100}$
$15 \times 100=1,500$
$1,500 \div 90=16.66$
So 15 is $16.7 \%$ of 90

## Example 3

12 is $30 \%$ of what number?
$\frac{12}{\text { ?or } n}=\frac{30 \%}{100}$
$12 \times 100=1,200$
$1,200 \div 30=40$
So 12 is $30 \%$ of 40
Percent of Change
A ratio that compares the change in quantity to the original amount
Equation: percent of change $=\frac{\text { amount of change }}{\text { original amount }}$
percent of increase $=\frac{\text { amount of increase }}{\text { original amount }}$
percent of decrease $=\frac{\text { amount of decrease }}{\text { original amount }}$
percent of error $=\frac{\text { amount of error }}{\text { actual amount }}$
Example 1: A Blue-Ray player was $\$ 280$. Now it is on sale for $\$ 220$. What is the percent of decrease?
percent of decrease $=\frac{\text { amount of } \text { decrease }=\$ 60}{\text { original amount }=\$ 280}$

Divide $\$ 60$ by $\$ 280$ to find the percent. $=0.214=21 \%$ (rounded)
Example 2: A Blue-Ray player was $\$ 120$. Now it is selling for $\$ 220$. What is the percent of increase?

$$
\text { percent of increase }=\frac{\text { amount of } \text { increase }=\$ 100}{\text { original amount }=\$ 120}
$$

Divide $\$ 100$ by $\$ 120$ to find the percent. $=0.833=83 \%$ (rounded)

## To Find Sales Tax

1) Turn the tax into a decimal.
2) Multiply the decimal by the total amount.
3) To find the final total, add the sales tax to the total amount

## Example:

What is the total cost on exercise equipment that costs $\$ 150$ with a sales tax of $6 \%$ ?
$6 \%=0.06$
$0.06 * 150=9.00 \leftarrow$ The tax is $\$ 9.00$
The total would be $\$ 159(\$ 150+\$ 9=\$ 159)$

## Markups and Selling Price

A store sells items for more that it pays for those items. The amount of increase is called the markup. The selling price is the amount the customer pays for the item.

Example: What is the selling price of a bicycle that the store bought for \$220 if the markup is 35\%

Find $35 \%$ of $\$ 220$.
$0.35 \times 220=\$ 77$
Add that to $\$ 220$ to get the selling price: $\$ 297$

## Discount or Markdown

Is the amount by which the regular price of an item is reduced. The sale price is the regular price minus the discount.
Method One: Multiply the original price by the discount and then subtract.
Method Two: Multiply the original price by the percent of the sale price.

Example 1: A Blue-Ray normally costs $\$ 22$. It is on sale for $25 \%$ off. What is the sale price?
$\$ 22 \times 0.25=\$ 5.50$
Subtract $\$ 5.50$ from $\$ 22$
$\$ 22$ - $\$ 5.50=\$ 16.50$
So the sale price is $\$ 16.50$

## Example 1, Method 2:

Multiply $\$ 22$ by $75 \%$ ( 0.75 )
$\$ 22 * 0.75=\$ 16.50$

## Example 2:

A cell phone is on sale for $30 \%$ off. If the sale price is $\$ 360$, what is the original price?
To solve this problem, use the Is/Of or Part/Whole equation
$\frac{\$ 360}{\text { whole }}=\frac{70 \%}{100}$

Notice that the $\$ 360$ is equal to $\mathbf{7 0 \%}$, not $\mathbf{3 0 \%}$.
In order to find the percent that it is equal to, we just subtract $30 \%$ from $100 \%$.
Cross-Multply
$\$ 360 * 100=\$ 36,000$
Divide by 70
$\$ 36,000 \div 70=\$ 514.29$
The original price was $\$ 514.29$

## Simple Interest

Principal is the amount of money deposited (or borrowed)
Simple interest is the amount earned (or paid) for the money

Formula
$\mathrm{I}=\mathrm{prt}$
Interest $=$ principal $*$ rate * time

## Example 1:

How much interest is earned on a savings account that pays $1.85 \%$ interest per year if the deposit amount is $\$ 500$ ?

Interest $=$ principal $*$ rate * time
Interest $=\$ 500 * 0.0185$ (changed percent into a decimal) * 1
$\$ 500 * 0.0185=9.25 * 1=\$ 9.25$
So that bank will pay $\$ 9.25$ interest on $\$ 500$ per year.

## Example 2:

How much interest is earned per month on a savings account that pays $1.85 \%$ interest per year if the deposit amount is $\$ 500$ ?

Using the previous example, we divide by 12 (since there are 12 months in a year) to find out how much interest is earned each month.
$\$ 9.25 \div 12=\$ 0.77$
Note: The trickiest part of finding interest is determining what to put in for time, so pay careful attention to what the question is asking.

Also note: In real-world applications, most interest rates are more complex (such as compound interest). In the bank example above, the interest would likely be compounded monthly, meaning that after 1 month, the account would be worth $\$ 500.77$. The $1.85 \%$ interest would then be calculated on the new balance.
